ABSTRACT

This study wanted to find out the hidden dimensions behind the bridge failures across the globe resulting to deaths using fractal analysis, a different lens to analyze available data. Fractal statistical analysis revealed that there were four (4) top and four (4) bottom of the list of bridges (or 3 percent of the 117 bridges) that caused the highest and lowest number of deaths, respectively. Examining the common characteristics in terms of the bridges' failures, the results implied that the bridges that were built in the past did not give the most durable bridge structures and they caused more casualties. Meanwhile, the bridges that were built recently gave the least number of casualties. This leads to the conclusion that the hidden dimension is innovative bridge construction engineering and technology to prevent structural failures in bridges.

KEYWORDS: bridge failures, engineering and technology, fractal, fractal analysis, innovative bridge construction.

1. INTRODUCTION

Fractal analysis is assessing the self-similarity, roughness or ruggedness of data. It consists of several methods to assign a fractal dimension and other fractal characteristics to a dataset which may be a theoretical dataset or a pattern or signal extracted from phenomena, including natural geometric objects, sound, market fluctuations, etc. [1]Fractal analysis is now widely used in all areas of science, but its important limitation is that coming up with the empirically determined fractal dimension does not necessarily attest that a pattern is fractal; rather, other needed characteristics have to be considered. [2]

Bridge failures are often tragic but are also fascinating for bridge engineers as they usually provide puzzles to solve and often lead to major changes in design, construction and management. [3] Bridge construction is a great challenge to all involved generally more so than in other areas of structural engineering, in spite of the fact that for most bridge systems the actions and effects of the forces involved are more easily determined than in some other load – bearing structures. Most bridge failures are cost by multiple factors. [4] Flood that damages the bridge piers might not have caused a collapse – except for a poor design flaw and poor maintenance. [5]

The collapse of bridges have the following common causes: seismic damages; bridge hydraulics which has something to do with bridge scour, being clogged by ice or debris, approach and road washouts, and just being pushed over by water; collision of boats as well as collision by trucks; earthquakes; fire; train crash; boat impact; flood; construction accidents; manufacturing defect; design defect; poor maintenance; odd occurrences; element of surprise; and by keeping bridges. [6], [7], [5],[3]

The more common causes and mechanisms of some bridge failures around the world are classified into natural factors (flood, scour, earthquake, landslide, wind, etc.) and human factors (improper design and construction method, collision, overloading, fire, corrosion, lack of inspection and maintenance, etc.). [8]

Similarities among collapsed bridges include bridges being classified as structurally deficient, bridges that have had the load carrying capacity lowered below the normal legal limit of vehicles, and bridges which have limited vertical clearance under the structure and a roadway under the structure. Age influences bridge failure for only specific causes of collapse. The causes of bridge failure were numerically determined and associated with

adverse effects of loss of life and average amount of traffic per day using the structure. Life loss occurred on about four (4) percent of bridge failure. [9]

Although it had been pointed out by various researchers the various reasons why bridges collapsed which caused the loss of lives of people, there had been no study yet regarding the factors behind the failure of bridges with the highest and lowest number of casualties. It is in this context that the researcher wanted to find the hidden dimensions behind the bridge failures across 117 countries resulting to deaths from 18th century to year 2000.

ISSN: 1674-8190

Moreover, this paper sought to determine the natural (fractal) state of the data, found out if there existed a fractal distribution, and analyze the hidden dimensions and fractality of the data.

2. MATERIALS AND METHODS

This study used fractal statistics to measure fractal dimension, the measure of the roughness or ruggedness of the data. Histograms of the data of deaths due to bridge failures were determined and inspected if it is exponential and fractally distributed to establish a certain pattern or model for the phenomenal trend of the deaths resulting from bridge failures worldwide.

In this study, the researcher used data from the study of W. [1] To determine the fractal dimension of the tabulated data set, the $\log \left(\frac{x}{\theta}\right)$ was first computed, obtained the mean of the log of x, and assessed the entire ruggedness index lambda (λ) of the data. From the world of concrete geometry, we migrate to the world of ideas or data by using the following formulas:

Exp.
$$(data/\emptyset)$$
 (i)

$$\lambda = 1 + \frac{1}{\bar{v}} \tag{ii}$$

Where:
$$\lambda = \log(no.\ of\ copies\ of\ x) / \log(s\ cale\ of\ x) = \log()/\log(\frac{x}{a})$$
 (iii)

$$\theta = \min\{x_i\} \tag{iv}$$

$$\lambda$$
 = the fractal dimension of the variable x (v)

It is not always easy to detect whether X is fractal or not based on its histogram. The fundamental theorem for fractal statistics was used: "X is fractal if and only if $\log (x/\theta)$ has an exponential distribution with rate parameter $\beta = \lambda - 1$." Thus, if the histogram of $y = \log (x/\theta)$ is not exponential, then X is not fractal.

This definition leads to:
$$f(x) = A(x/\theta)^-, \lambda > 0$$
 and $x > \theta$ (vi

As the density or probability distribution of x, large values of x will have smaller probabilities of occurrence, while small values of x will have larger probabilities of occurrence. In order for X to have a probability distribution f(x), it is required that:

$$A = (\lambda - 1)/\theta \text{ and } > 1; \theta > 0$$
 (vii)

The fractal dimensions of fractal random variables X will have to be greater than 1 in order for a probability distribution to exist.

3. RESULTS AND DISCUSSION

The data presented in this section shows the frequency distribution and exponential distribution of the deaths global bridge failures.

In analyzing the data of the number of deaths resulting from bridge failures, the natural (fractal) dimension was determined to show roughness or ruggedness of the distribution using fractal statistical analysis (FSA). It was first established that the dataset was fractal.

Table 1 presents the list of the worldwide bridge failures resulting to deaths.

Table 1. Worldwide bridge failures resulting to deaths

frequency distributions of bridge failures causing deaths and the fractal distribution of the same dataset, respectively.

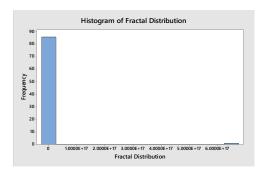

Figure 1.Frequency distribution

Figure 2.Exponential distribution

As gleaned from Fig. 1, the frequency distribution of bridge failures resulting deaths is positively skewed, but it cannot be safely assumed that the data set is really fractal.

The exponential of (x/θ) was used to ascertain that the data set was fractal. Fig. 2, the exponential representation of the percent of the number of bridges, verified that the dataset was indeed fractal.

Table 2 below shows the number of bridge failures causing deaths, the mean percentage, the minimum value, and the computed fractal dimension of the distribution of global bridge failures causing deaths.

Table 2. Distribution of bridge failures

N	Mean	Minimum Value (θ)	Fractal Dimension (λ)
117	44.1	1.0	1.02268

Table 2 shows that, among the 117 bridges that failed across the globe, the mean percentage was 44.1 with a minimum percentage value of 1.00 percent. The computed fractal dimension lambda reached 1.02268. This implies that the distribution of the bridges across the globe causing deaths due to failure deviated from normality by 3 percent.

Tables 3 presents the ranking of the four (4) top list of bridges causing the highest number of deaths, or the 3 percent of the 117 bridges across the globe.

Table 3. Top four (4) bridges with highest death count

Name of Bridge	Death Count
Eitai Bridge / Eitai-bashi (Japan)	1500
Angers Bridge (France)	226
Ulyanovsk railway bridge (USSR)	177
Whangaehu River Rail Bridge (New Zealand)	151

The Tabled discloses that the top 4 bridges with the highest number of deaths were Eitai Bridge (Eitai-bashi), Angers Bridge, Ulyaneusk Railway Bridge, and Whangaehu River Rail Bridge. The said bridges had been built during the latter part of the 18th century to the middle part of the 19th century.[1] This implies that the bridges used the old bridge construction engineering and technology.

Tables 4 presents the ranking of the bottom four (4) bridges with the lowest number of deaths, or the 3 percent of the 117 bridges across the globe.

Table 4. Top four (4) bridges with lowest death count

Name of Bridge	Death
Kansas Avenue Bridge (United States)	1
Reichsbrücke Bridge (Vienna)	1
Aschaffenburg Main River Freeway Bridge (Germany)	1

ISSN: 1674-8190

Oakland Bay Bridge (San Francisco)

The top 4 bridges with the lowest number of deaths were the Kansas Avenue Bridge, Reichsbrücke Bridge, Aschaffenburg Main River Freeway Bridge, and Oakland Bay Bridge. Each of these bridge failures caused only one (1) death. Those bridges were built during the latter part of the 19th century, specifically from 1976 to 1989.[1] This implies that those bridges used innovative concepts or advanced bridge construction engineering and technology.

4. CONCLUSION

The Fractal Statistical Analysis revealed that frequency distribution of global bridge failures resulting deaths is fractal. The hidden dimension behind such incidence could be attributed to bridge construction engineering and technology. The bridge failures with the highest number of deaths could be attributed to the use of old bridge construction engineering and technology. On the other hand, the use of innovative concepts or advanced technology in bridge construction engineering and technology contributed much to low death count resulting from bridge failures.

5. ACKNOWLEDGEMENTS

This work would not have been made possible without the concerted effort of all the researchers who have shown their genuine commitment and support thereby motivating themselves to pursue this academic endeavor despite the challenges they encountered. They also greatly recognized the support and inspiration given by their university President, Dr. Victor C. Cañezo, who had driven all faculty to undertake intellectual endeavors like this to bring the university to greater heights. Above all, to the Almighty Father, for being the source of strength and wisdom therefore making this work a success.
